COOL MILK IN HOT WEATHER

Series of Experiments on Duration of Survival of Milk in Summer Heat

DAIRY FACTS

A series of experiments conducted by the Kansas State College were designed to test the influence of temperature on the survival of milk. These experiments were conducted under conditions in the summer of 1920. The following are some of the results obtained.

1. Milk that was cooled to 40°F in a refrigerator and kept at this temperature for 24 hours showed no evidence of bacterial contamination.

2. Milk that was cooled to 50°F and kept at this temperature for 24 hours showed some bacterial contamination.

3. Milk that was cooled to 60°F and kept at this temperature for 24 hours showed a rapid increase in bacterial contamination.

4. Milk that was cooled to 70°F and kept at this temperature for 24 hours showed a rapid increase in bacterial contamination and a rapid decrease in survival time.

These experiments show that milk should be kept at a temperature as low as possible, preferably at 40°F, to insure maximum survival time.

Feeding Lone Corn Silage

FEEDING LONE CORN SILAGE

Corn silage may be fed in the ground, but it is better to break it up and form it into a bed and then to turn the feeders out on the ground. It is better to feed the corn silage in the afternoon or evening, and then to feed it in the morning or evening.

CHAPTER I

I CAN'T FIGHT ANY MORE

The broker came out of the door of the Eastern Union exchange, an old man of sixty or more. He was dressed in a blue frock coat, white shirt, and black silk hat. His face was clean-shaven, and his hair was white. He looked like a man who had been in business for many years.

"I'm here to get some money," he said.

The broker smiled at him.

"I know," he said. "You want to get some money."
